

Remorq — pooled pallet freight across Western Europe

The Problem

One in four trucks in Europe runs empty, and those carrying cargo are on average only 63% full. Palletised freight — between 2 and 12 pallets, too little for a full truckload, too much for a parcel network — is where that waste concentrates.

A shipper sending 6 pallets has two options: pay for a full truck they will not fill, or use a traditional groupage network that multiplies handling. The second route means 4 to 7 handling steps, 3 to 5 days in transit, and a 2–4% damage rate.

Our Solution

Remorq pools shipments from several shippers onto the same truck, with no hub in between. Our matching engine reads incoming orders and builds two- or three-stop routes that stay economically viable for the carrier.

In practice: a shipper books 6 pallets from Lyon to Antwerp. In under two minutes the system finds two compatible shipments on time window and route, assembles the load and confirms a firm price. The goods never leave the truck between origin and destination.

The Market

Palletised freight is worth roughly €38B a year in Western Europe. Most of it still moves through groupage networks run on the same principles as twenty years ago.

We are starting with France, the Benelux and western Germany — about €14B — where industrial density makes matching most effective.

Competition

Incumbent groupage networks dominate the segment. Their strength is physical coverage; their weakness is the hub, which forces the handling steps. Several digital platforms offer on-demand full truckload, but none addresses palletised freight specifically.

We do not claim an unassailable technology: our matching engine builds on well-documented optimisation methods. Our lead comes from order-book density — the more simultaneous shipments, the better the matches — and from having started with the densest corridors.

The Team

Claire Vanderbeke spent nine years running groupage operations at one of Europe's five largest carriers, with responsibility for 1,200 daily departures. Tomas Ruiz built and led the route optimisation team at a delivery platform operating in eleven countries. The two worked on this problem for eighteen months before incorporating.

We are fourteen people today, six of them in operations — this business does not fully automate on day one.

Traction

- 31 months of operation
- €34M billed volume over the last twelve months

- 7% month-on-month growth over the last six months
- 890 active shippers, 140 of them billing more than €15,000 per month
- 12-month retention: 86%
- average load factor: 84%, against an industry average of 63%
- 4,100 partner carriers

Business Model

We collect what the shipper pays and remit to the carrier. Gross take rate is 14%, which on last year's volume is €4.8M. After direct operating costs — support, claims handling, cargo insurance — 6.2 points remain, or €2.1M, up from 4.8 points a year ago.

We report billed volume and net contribution separately because they are not the same number and we would rather you did not have to work that out yourself.

That margin is structurally thin: we are a pass-through, and our revenue is a narrow slice of a large one. It improves as density grows, since the cost of processing a shipment falls when matching gets easier. We have not yet shown that it holds beyond our three main corridors.

Go-To-Market

Direct sales to supply chain directors at mid-sized manufacturers. Average cycle of 7 weeks. Acquisition cost of €2,100 per active shipper, paid back in 4.5 months.

Funding

We are raising €12M to open three additional corridors, grow the operations team to fifteen, and industrialise the matching engine, which today is manually supervised beyond three stops.
