

# Chainwright Protocol — decentralised infrastructure for verifiable compute

## The Problem

Computation today is trusted, not verified. When a workload runs on a centralised provider, the party consuming the result has no cryptographic assurance that the computation was performed as specified. This is an unsolved trust primitive at the base of the entire digital economy, and it becomes critical as autonomous agents begin transacting on behalf of users.

The industry has accepted this trust assumption because there was no alternative. There now is.

## Our Solution

Chainwright is a permissionless protocol coordinating a decentralised network of compute providers, with cryptographic verification of execution and on-chain settlement.

The architecture is modular. A consensus layer handles provider coordination and slashing. An availability layer handles state. An execution layer runs workloads inside attestable environments, producing succinct proofs that are verified on-chain at constant cost regardless of workload size.

The protocol is governed by the CWR token. Providers stake to participate, consumers pay in CWR, and the treasury is directed by token-holder governance through a delegated voting mechanism.

We are building the trust layer for the machine economy.

## The Market

Cloud compute is a \$700B market. Verifiable compute is a category that does not yet exist and will, in our view, absorb a meaningful share of it as regulatory and agentic pressure makes unverified execution untenable.

The addressable opportunity is therefore the intersection of cloud infrastructure and the \$2.3T digital asset market.

## Competition

Several projects address adjacent layers: decentralised storage, decentralised GPU marketplaces, general-purpose proving systems. None composes the three layers into a single verifiable execution environment with economic security.

Our differentiation is architectural and is described in the whitepaper.

## The Team

Dmitri Volkov previously led protocol research at a layer-one foundation. Sofia Andersson was a distributed systems engineer and has contributed to two well-known open-source consensus implementations. The wider contributor group includes nine engineers, several of whom participate pseudonymously, which is normal in this ecosystem.

## Traction

- 41,000 members in the community across Discord and Telegram

- testnet live with 1,900 registered provider nodes
- 6.2 million testnet transactions processed
- three ecosystem partnerships announced
- whitepaper v2 published, 14,000 downloads

Mainnet is targeted for the second half of next year.

### **Business Model**

Protocol fees accrue to the treasury and to stakers. Fee capture is a function of network usage, which is a function of adoption.

The token distribution allocates 22% to the team and early contributors with a four-year vest, 18% to the treasury, and the remainder to ecosystem incentives and public distribution.

### **Go-To-Market**

Ecosystem grants, developer relations, and integration partnerships with wallets and agent frameworks.

### **Funding**

We are raising \$14M at a \$180M fully diluted valuation to fund mainnet launch and ecosystem incentives.
